The possibility that primordial black holes (PBHs) represent all of the dark matter (DM) in the Universe and explain the coalescences of binary black holes detected by LIGO/Virgo has attracted a lot of attention. PBHs are generated by the enhancement of scalar perturbations which inevitably produce the induced gravitational waves (GWs). We calculate the induced GWs up to the third-order correction which not only enhances the amplitude of induced GWs, but also extends the cutoff frequency from $2k_*$ to $3k_*$. Such effects of the third-order correction lead to an around 10% increase of the signal-to-noise ratio (SNR) for both LISA and pulsar timing array (PTA) observations, and significantly widen the mass range of PBHs in the stellar mass window accompanying detectable induced GWs for PTA observations including IPTA, FAST and SKA. And hence the null detections of the induced GWs by LISA and PTA experiments will exclude the possibility that all of the DM is comprised of PBHs and the GW events detected by LIGO/Virgo are generated by PBHs.

Various independent cosmological observations indicate the existence of dark matter (DM) in our Universe. The nature of DM remains highly elusive despite decades of dedicated searches. However, cosmological observations are only sensitive to the macroscopic properties of DM. Even though a new elementary particle is postulated in standard DM scenarios, primordial black hole (PBH) DM has attracted a lot of attention [1–4], ever since the first direct detection of gravitational waves (GWs) from a binary black hole (BBH) coalescence [5]. The primordial-origin BBHs are appealing candidates of LIGO/Virgo BBHs if the abundance of stellar mass PBHs in DM is a few part in thousand [6–8]. And there are various powerful observational constraints in literature [8–25], but a substantial window remains open for PBHs as dark matter in the approximate range $[10^{-16}, 10^{-14}] \cup [10^{-13}, 10^{-12}] M_\odot$. See a recent summary in [8].

PBHs are supposed to form from the enhancement of the scalar perturbations [26, 27]. The process during which the PBHs are formed would be inevitably accompanied by GWs [28–35]. These so-called induced GWs are driven by scalar perturbations during radiation-dominated (RD) era and could leave detectable signal at present for testing the hypothesis of PBH DM [3, 36–44]. Recently, a semi-analytical expression for the GWs induced by second-order scalar perturbations has been derived in [45], triggering an upsurge in exploring the possibility to detect the primordial non-Gaussianity through induced GWs [46, 47] and the bispectrum of the induced GWs [48–50]. PBHs could have been produced during RD era when relatively large scalar perturbations with amplitudes $\mathcal{O}(0.01 - 0.1)$ re-entered the Hubble horizon [51–55]. The non-linearity is an intrinsic property for

gravity in general relativity, and therefore the higher-order corrections to the scalar induced GWs are expected to be important. However, previous studies only focused on the GWs induced by second-order scalar perturbations, and as far as we know, no higher-order effects have been taken into account in literature. In this letter, we derive a semi-analytical result of the induced GWs up to third-order, and find that the third-order correction would be detectable by some future GW detectors, such as LISA [56], IPTA [57], FAST [58] and SKA [59], and has significant observational implications.

The perturbed metric in the FRW spacetime with Newtonian gauge takes the form, [35],

$$ds^2 = a^2 \left\{ -(1+2\phi)d\eta^2 + \left[(1-2\phi)\delta_{ij} + \frac{h_{ij}}{2}\right] dx^i dx^j \right\},$$ (1)

where ϕ and h_{ij} are the scalar and tensor perturbations respectively. The scalar perturbation in Fourier space has a solution [3, 38, 45, 60]

$$\phi_{\boldsymbol{k}}(\eta) \equiv \phi_{\boldsymbol{k}} T(k\eta),$$ (2)

where $\phi_{\boldsymbol{k}}$ is the primordial perturbation and $T(k\eta)$ is the transfer function

$$T(k\eta) = \frac{9}{(k\eta)^2} \left[\frac{\sin(k\eta/\sqrt{3})}{k\eta/\sqrt{3}} - \cos(k\eta/\sqrt{3})\right],$$ (3)

which oscillates and decays as $\sim 1/\eta^2$ in the RD era. In order to extract the induced GWs up to the third-order, it is necessary to expand Einstein equations up to the fourth-order (perturbations are performed utilizing the `xPand` [61] package). After a tedious but straightforwards

computation, the evolution of the GWs up to the fourth-order is given by

$$h_{ij}'' + 2\mathcal{H}h_{ij}' - \nabla^2 h_{ij} = -4\mathcal{T}_{ij}^{\ell m}S_{\ell m}, \qquad (4)$$

where the prime denotes the derivative with respect to the conformal time η, $\mathcal{H} \equiv a'/a$ is the conformal Hubble parameter, and $\mathcal{T}_{ij}^{\ell m}$ is the projection operator [62] onto the transverse and traceless tensor. Although Eq. (4) has the same form as the evolution of GWs at second-order (see *e.g.* [38, 62]), the source term $S_{ij} = S_{ij}^{(2)} + S_{ij}^{(3)} + S_{ij}^{(4)}$ has been calculated up to fourth-order as follows

$$S_{ij}^{(2)} = 4\phi\partial_i\partial_j\phi + 2\partial_i\phi\partial_j\phi - \frac{1}{\mathcal{H}}\partial_i\left(\phi + \frac{\phi'}{\mathcal{H}}\right)\partial_j\left(\phi + \frac{\phi'}{\mathcal{H}}\right), \qquad (5)$$

$$S_{ij}^{(3)} = \frac{1}{\mathcal{H}}\left(12\mathcal{H}\phi - \phi'\right)\partial_i\phi\partial_j\phi - \frac{1}{\mathcal{H}^3}\left(4\mathcal{H}\phi - \phi'\right)\partial_i\phi'\partial_j\phi' + \frac{1}{3\mathcal{H}^4}\left(2\partial^2\phi - 9\mathcal{H}\phi'\right)\partial_i\left(\mathcal{H}\phi + \phi'\right)\partial_j\left(\mathcal{H}\phi + \phi'\right), \qquad (6)$$

$$\begin{aligned}
S_{ij}^{(4)} =& 16\phi^3\partial_i\partial_j\phi + \frac{1}{3\mathcal{H}^3}\Big[2\phi'\partial^2\phi - 9\mathcal{H}\phi'^2 - 8\mathcal{H}\phi\partial^2\phi \\
&\qquad\qquad + 18\mathcal{H}^2\phi\phi' + 96\mathcal{H}^3\phi^2\Big]\partial_i\phi\partial_j\phi \\
&+ \frac{2}{3\mathcal{H}^5}\Big[-\phi'\partial^2\phi + 3\mathcal{H}\phi'^2 + 4\mathcal{H}\phi\partial^2\phi \\
&\qquad\qquad + 3\mathcal{H}^2\phi\phi' - 12\mathcal{H}^3\phi^2\Big]\partial_i\phi'\partial_j\phi' \\
&+ \frac{1}{3\mathcal{H}^6}\Big[-16\partial^2\phi - 3\phi\partial_k\phi'\partial^k\phi' + 120\mathcal{H}\phi'\partial^2\phi \\
&\qquad - 6\mathcal{H}\partial_k\phi\partial^k\phi' + 144\mathcal{H}^2\phi\partial^2\phi - 180\mathcal{H}^2\phi'^2 \\
&\qquad + 33\mathcal{H}^2\partial_k\phi\partial^k\phi - 540\mathcal{H}^3\phi\phi' - 144\mathcal{H}^4\phi^2\Big] \\
&\times \partial_i\left(\mathcal{H}\phi + \phi'\right)\partial_j\left(\mathcal{H}\phi + \phi'\right). \qquad (7)
\end{aligned}$$

After solving Eq. (4) in Fourier space by Green's function, we can use the two-point correlation of the GWs to calculate their power spectrum, namely

$$\langle h(\boldsymbol{k},\eta)h(\boldsymbol{k}',\eta)\rangle \equiv \frac{2\pi^2}{k^3}\mathcal{P}_h(k,\eta)\delta(\boldsymbol{k}+\boldsymbol{k}'). \qquad (8)$$

The angle brackets stand for ensemble average which can be calculated using timing average instead. The GW energy density, $\rho_{GW} = \int \rho_{GW}(k,\eta)\,\mathrm{d}\ln k$, can be evaluated as [63]

$$\rho_{GW} = \frac{M_p^2}{16a^2}\left\langle \overline{\partial_k h_{ij}\partial^k h^{ij}}\right\rangle, \qquad (9)$$

where the overline stands for the average of the oscillating effect of the time-varying phase and M_p is the Planck mass. The dimensionless GW energy density parameter

Ω_{GW} is defined as the energy density of GWs per logarithmic frequency normalized by the critical density ρ_{cr},

$$\Omega_{GW}(\eta,k) \equiv \frac{\rho_{GW}(k,\eta)}{\rho_{cr}} = \frac{1}{12}\left(\frac{k}{\mathcal{H}}\right)^2\overline{\mathcal{P}_h(k,\eta)}, \qquad (10)$$

where we have summed over the two polarization modes of $+$ and $\times$. Solving Eq. (4) by the Green's function method, one obtains [38]

$$h(\boldsymbol{k},\eta) = \frac{1}{ka(\eta)}\int \mathrm{d}\tilde\eta \sin(k\eta - k\tilde\eta)a(\tilde\eta)\mathcal{S}_{\boldsymbol{k}}(\tilde\eta), \qquad (11)$$

where $\mathcal{S}_{\boldsymbol{k}}(\eta) \equiv -4e^{ij}(\boldsymbol{k})\tilde{S}_{ij}(\boldsymbol{k},\eta)$ with $\tilde{S}_{ij}(\boldsymbol{k},\eta)$ being the source term transformed into Fourier space. The polarization tensors $e_{ij}(\boldsymbol{k})$ are defined as $(e_ie_j - \bar{e}_i\bar{e}_j)/\sqrt{2}$ and $(e_i\bar{e}_j + \bar{e}_ie_j)/\sqrt{2}$ for $+$ and $\times$ polarizations respectively, where $e_i(\boldsymbol{k})$ and $\bar{e}_i(\boldsymbol{k})$ are two independent unit vectors orthogonal to $\boldsymbol{k}$. Since ϕ is related to the comoving curvature perturbation ζ by $\phi = (2/3)\zeta$ on superhorizon scales, $\Omega_{GW}(\eta,k)$ can be calculated using the power spectrum of the comoving curvature perturbation, $\mathcal{P}_\zeta(k)$, defined by

$$\langle \zeta_{\boldsymbol{k}}\zeta_{\boldsymbol{k}'}\rangle \equiv \frac{2\pi^2}{k^3}\mathcal{P}_\zeta(k)\delta(\boldsymbol{k}+\boldsymbol{k}'). \qquad (12)$$

From now on we will dedicated to the following monochromatic power spectrum

$$\mathcal{P}_\zeta(k) = Ak_*\delta\left(k - k_*\right), \qquad (13)$$

to illustrate the effects of third-order correction. Here A is an overall normalization coefficient and k_* is the wavenumber at which the power spectrum has a δ-function peak. Note that it is robust to neglect the contribution of the long wavelength modes on the CMB scales, because not only the time delay effect of the long wavelength will not affect the GWs power spectrum [49], but also the long wavelength mode is well outside the horizon during the formation of PBHs and thus should not affect any local physical processes. On the other hand, the δ-spectrum also corresponds to a monochromatic PBH formation. The formation of PBHs is a threshold process where the comoving curvature perturbation $\zeta(\boldsymbol{x})$ exceeds a threshold value ζ_c and causes an overdensed region. The possibility of forming a PBH can be evaluated statistically by integrating the probability density function over the threshold region [64]

$$\beta = \int_{\zeta_c}^{+\infty}\frac{\mathrm{d}\zeta}{\sqrt{2\pi}\sigma}e^{-\zeta^2/2\sigma^2} = \frac{1}{2}\mathrm{erfc}\left(\frac{\zeta_c}{\sqrt{2A}}\right), \qquad (14)$$

where $\zeta_c \simeq 1$ is the threshold value [65–68] to form a PBH and $\sigma^2 \equiv \langle\zeta^2\rangle = \int \mathcal{P}_\zeta(k)\mathrm{d}\ln k = A$ is the variance of the curvature perturbation. For monochromatic PBHs, the possibility to form a single PBH, β, is equivalent to the

abundance of PBHs which is related to the fraction of PBHs by [69]

$$f_{\mathrm{pbh}} \simeq 2.5 \times 10^8 \beta \left(\frac{g_*^{\mathrm{form}}}{10.75} \right)^{-\frac{1}{4}} \left(\frac{m_{\mathrm{pbh}}}{M_\odot} \right)^{-\frac{1}{2}}, \quad (15)$$

where g_*^{form} is the effective degrees of freedom when PBHs are formed, and the mass of the PBH roughly equals to the horizon mass, namely

$$\frac{m_{\mathrm{pbh}}}{M_\odot} \approx 2.3 \times 10^8 \left(\frac{3.91}{g_*^{\mathrm{form}}} \right)^{1/6} \left(\frac{H_0}{f_*} \right)^2, \quad (16)$$

where we have used $k_* = aH_* = 2\pi f_*$ and H_0 is the Hubble constant at present.

For the δ-spectrum in Eq. (13), the source terms in Fourier space are given by

$$\mathcal{S}_{\boldsymbol{k}}^{(2)}(\eta) \equiv \int \frac{\mathrm{d}^3 p}{(2\pi)^{3/2}} \mathbf{e}(\boldsymbol{p}, \boldsymbol{p}) f_2(k_* \eta) \zeta_{\boldsymbol{p}} \zeta_{\boldsymbol{k}-\boldsymbol{p}}, \quad (17)$$

$$\mathcal{S}_{\boldsymbol{k}}^{(3)}(\eta) \equiv \int \frac{\mathrm{d}^3 p \mathrm{d}^3 q}{(2\pi)^3} \mathbf{e}(\boldsymbol{p}, \boldsymbol{q}) f_3(k_* \eta) \zeta_{\boldsymbol{p}} \zeta_{\boldsymbol{q}} \zeta_{\boldsymbol{k}-\boldsymbol{p}-\boldsymbol{q}}, \quad (18)$$

$$\mathcal{S}_{\boldsymbol{k}}^{(4)}(\eta) \equiv \int \frac{\mathrm{d}^3 p \mathrm{d}^3 q \mathrm{d}^3 l}{(2\pi)^{9/2}} \left[\mathbf{e}(\boldsymbol{l}, \boldsymbol{l}) + \mathbf{e}(\boldsymbol{p}, \boldsymbol{q}) \right] f_4(k_* \eta)$$
$$\times \zeta_{\boldsymbol{p}} \zeta_{\boldsymbol{q}} \zeta_{\boldsymbol{l}} \zeta_{\boldsymbol{k}-\boldsymbol{p}-\boldsymbol{q}-\boldsymbol{l}}, \quad (19)$$

where we have defined $\mathbf{e}(\boldsymbol{p}, \boldsymbol{q}) \equiv e^{ij}(\boldsymbol{k}) p_i q_j$, and $f_i(x)$ $(i = 2, 3, 4)$ have the following functional forms

$$f_2(x) = \frac{8}{9} \left(3T^2 + 2xTT' + x^2 T'^2 \right), \quad (20)$$

$$f_3(x) = -\frac{64}{81} \Big[\left(x^2 - 18 \right) T^3 + 2x \left(3 + x^2 \right) T^2 T'$$
$$+ x^2 \left(15 + x^2 \right) TT'^2 + 3x^3 T'^3 \Big], \quad (21)$$

$$f_4(x) = \frac{8}{729} \Big[\left(720 - 29x^2 + 16x^4 \right) T^4$$
$$+ 4x \left(144 + 73x^2 + 8x^4 \right) T^3 T'$$
$$+ 2x^2 \left(864 + 219x^2 + 8x^4 \right) T^2 T'^2$$
$$+ 4x^3 \left(198 + 31x^2 \right) TT'^3 + x^4 \left(108 + 7x^2 \right) T'^4 \Big]. (22)$$

The explicit expression for transfer function $T = T(x)$ can be found in Eq. (3). From Eqs. (8) and (11), we see that only $\langle \mathcal{S}_{\boldsymbol{k}}^{(2)} \mathcal{S}_{\boldsymbol{k}'}^{(2)} \rangle$ contributes to second-order induced GWs. Meanwhile, both $\langle \mathcal{S}_{\boldsymbol{k}}^{(3)} \mathcal{S}_{\boldsymbol{k}'}^{(3)} \rangle$ and $\langle \mathcal{S}_{\boldsymbol{k}}^{(2)} \mathcal{S}_{\boldsymbol{k}'}^{(4)} \rangle$ contribute to the third-order correction. Following the pioneering work of [45], for the δ-spectrum in Eq. (13), we obtain

$$\Omega_{\mathrm{GW}}(\eta, k) = \frac{A^2}{192\tilde{k}^2} \left[\overline{I_2^2} M_1 + A \left(M_2 \overline{I_3^2} + M_1 \overline{I_2 I_4} \right) \right], \quad (23)$$

where an overbar denotes the oscillation average [45] and I_i $(i = 2, 3, 4)$ are defined as

$$I_i = \lim_{x \to \infty} \int_0^x \mathrm{d}\tilde{x} \, f_i \left(\frac{\tilde{x}}{\tilde{k}} \right) \frac{\tilde{x}}{x} \sin(x - \tilde{x}), \quad (24)$$

which reflects the phase oscillation of the GWs. For convenience, we have defined some dimensionless parameters, i.e. $\tilde{k} \equiv k/k_*$, $x \equiv k\eta$ and $\tilde{x} \equiv k\tilde{\eta}$. Similar to [45], Eq. (24) can be analytically integrated by multiple usages of the trigonometric addition theorem and the properties of sine integral $\mathrm{Si}(\theta)$ and cosine integral $\mathrm{Ci}(\theta)$. The angle integrals M_1 and M_2 in Eq. (23) are defined as

$$M_1(k) = \left(4 - \tilde{k}^2 \right)^2 \Theta(2 - \tilde{k}), \quad (25)$$

$$M_2(k) = \frac{1}{\pi^2} \int_{p_{\mathrm{min}}}^{p_{\mathrm{max}}} \mathrm{d}\tilde{p} \int_0^{2\pi} \mathrm{d}\alpha \int_0^{2\pi} \mathrm{d}\phi M_0 \Theta(\Delta), (26)$$

where Θ is the Heaviside step function, $p_{\mathrm{min}} = |1 - \tilde{k}|$, and $p_{\mathrm{max}} = \min(2, 1 + \tilde{k})$. Due to its complexity, the expression of M_2 is evaluated numerically and the definition of M_0 and Δ are given by

$$\Delta = 4\mu^2 + 4(1 - \mu^2) \cos(\alpha - \phi)^2 - \tilde{p}^2, \quad (27)$$

$$M_0 = \sum_{i=1}^{2} \frac{(1 - \nu_i^2)}{\left| \mu \sqrt{1 - \nu_i^2} - \nu_i \sqrt{1 - \mu^2} \cos(\alpha - \phi) \right|}$$
$$\Big[(1 - \nu_i^2)^{\frac{3}{2}} \cos^2 2\alpha + 2\tilde{p}^3 (1 - \mu^2)^{\frac{3}{2}} \cos 2\phi \cos(\alpha + \phi)$$
$$- 2\tilde{p}(1 - \nu_i^2)(1 - \mu^2)^{\frac{1}{2}} \cos 2\alpha \cos(\alpha + \phi)$$
$$- \tilde{p}^2 (1 - \mu^2)(1 - \nu_i^2)^{\frac{1}{2}} \cos(\alpha + \phi)^2 \Big], \quad (28)$$

where μ and ν_i $(i = 1, 2)$ are defined as

$$\mu = \frac{\tilde{p}^2 + \tilde{k}^2 - 1}{2\tilde{p}\tilde{k}}, \quad (29)$$

$$\nu_{1,2} = \frac{\tilde{p}\mu \pm \sqrt{1 - \mu^2}|\cos(\alpha - \phi)|\sqrt{\Delta}}{2 \left((1 - \mu^2) \cos(\alpha - \phi)^2 + \mu^2 \right)}. \quad (30)$$

Note that M_1 is originated from the $\langle \mathcal{S}_{\boldsymbol{k}}^{(2)} \mathcal{S}_{\boldsymbol{k}'}^{(2)} \rangle$ and $\langle \mathcal{S}_{\boldsymbol{k}}^{(2)} \mathcal{S}_{\boldsymbol{k}'}^{(4)} \rangle$ terms, and indicates a cutoff frequency at $k = 2k_*$; while M_2 is originated from the $\langle \mathcal{S}_{\boldsymbol{k}}^{(3)} \mathcal{S}_{\boldsymbol{k}'}^{(3)} \rangle$, and indicates a cutoff at $k = 3k_*$. Therefore the third-order correction not only enhances the amplitude of GW energy density, but also extends the cutoff frequency from $2k_*$ to $3k_*$.

Note that Eq. (23) is only valid from the horizon re-entry to matter-radiation equality. Because the energy density of GWs decays as radiation, current density parameter of GWs can be approximated by [70]

$$\Omega_{\mathrm{GW}}(\eta_0, f) \simeq \Omega_r \times \Omega_{\mathrm{GW}}(\eta, f), \quad (31)$$

where Ω_r is the density parameter of radiation at present. From Eq. (16), heavier masses of PBHs corresponds to lower peak frequencies of induced GWs. Fig. 1 shows the GWs induced by scalar perturbation up to third order compared with the sensitivity curves of LISA, IPTA, FAST and SKA. Because a substantial windows for PBH as all of DM in the approximate range $[10^{-16}, 10^{-14}] \cup [10^{-13}, 10^{-12}] M_\odot$ is still available, for example, we choose
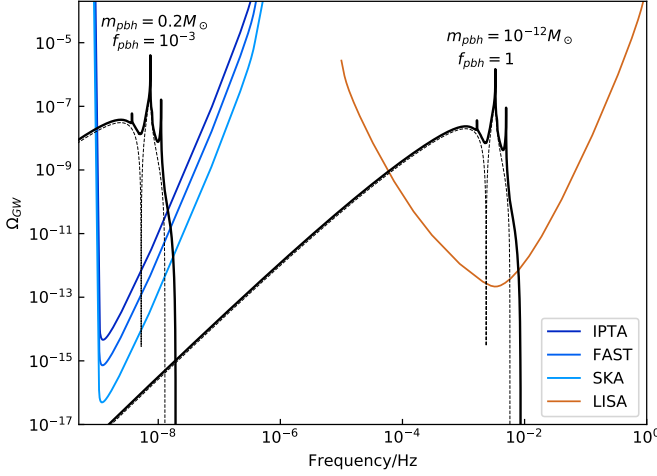

FIG. 1. The GW density parameter of scalar induced GWs along with the power-law integrated sensitivity curves [71] of LISA, IPTA, FAST and SKA. The black solid (dashed) lines represent Ω_{GW} induced by scalar perturbations up to third-order (second-order). We assume IPTA, FAST and SKA last for the same observation time of 30 years, and other settings of these PTA projects can be found in Table 5 of [72].

$m_{\mathrm{pbh}} = 10^{-12} M_\odot$ and $f_{\mathrm{pbh}} = 1$ and then the peak frequency of the induced GW is $f \sim 10^{-3}$ Hz which is within the LISA frequency band. In addition, roughly speaking, since the abundance of stellar mass PBHs has been constrained to be less than 0.01 [8], we choose $m_{\mathrm{pbh}} = 0.2 M_\odot$ and $f_{\mathrm{pbh}} = 10^{-3}$, and then the peak frequency of induced GWs is just located at the PTA frequency band. In fact, since Eqs. (14) and (15) imply $f_{\mathrm{pbh}} \propto \sqrt{A} \exp(-A^{-1})$ for a relatively small value of A, even decreasing f_{pbh} by multiple orders, the consequent value of A will almost not change. Therefore the amplitude of Ω_{GW} will almost be irrespective with the choice of f_{pbh} unless f_{pbh} is dramatically much smaller than our choice in Fig. 1. From Fig. 1, we also see that the third-order correction not only enhances the magnitude of Ω_{GW} (especially smooth the deep valley at $f = \sqrt{2/3} f_*$ from the second-order effect), but also extends cutoff frequency from $2f_*$ to $3f_*$. Besides, for a narrow spectrum, it would also generate two new resonant peaks at $f = (1/\sqrt{3}) f_*$ and $f = \sqrt{3} f_*$. Moreover, the typical $\Omega_{\mathrm{GW}}(\eta_0, f)$ in Fig. 1 shows that the third-order correction of the induced GWs is also far beyond the sensitivity curves for both LISA and PTA observations, rendering third-order correction being detectable and thus, indispensable in testing the hypothesis of PBHs.

In order to quantitatively evaluate the effects of the third-order correction in observations, we need to estimate the SNR, ρ, for different GW experiments. For

LISA, it is given by [71]

$$\rho = \sqrt{T} \left[\int \mathrm{d}f \left(\frac{\Omega_{\mathrm{GW}}(f)}{\Omega_n(f)} \right)^2 \right]^{1/2}, \qquad (32)$$

where $\Omega_n(f) = 2\pi^2 f^3 S_n/(3H_0^2)$ and S_n is the strain noise power spectral density [73]. For PTA observations, if we assume pulsars are distributed homogeneously and all pulsars have the same noise characteristics, the SNR is given by [74]

$$\rho = \sqrt{2T} \left(\sum_{I,J}^M \chi_{IJ}^2 \left[\int \mathrm{d}f \left(\frac{\Omega_{\mathrm{GW}}(f)}{\Omega_n(f) + \Omega_{\mathrm{GW}}(f)} \right)^2 \right] \right)^{1/2}, \qquad (33)$$

where χ_{IJ} is the Hellings and Downs coefficient for pulsars I and J [75]. Fig. 2 shows the expected SNR obtained for LISA and PTA experiments, and indicates that the third-order correction would raise the SNR as expected. For LISA, we expect around a 15% increase in the relative SNR; while for PTA observations, we expect the increase is more than 5% and could even reach 20% for stellar mass PBHs. Most importantly, since the third-order correction will extend the cutoff frequency from $2k_*$ to $3k_*$, the induced GWs accompanying heavier PBHs are supposed to be detected by PTA observations. For instance, as shown in Fig. 2, the third-order correction will extend the largest detectable mass of PBHs from around $30 M_\odot$ to $65 M_\odot$, which will be an invaluable complimentary tool to test the PBH scenario in addition to the analysis LIGO/Virgo.

In this letter, we compute the third-order correction to the induced GWs generated by the scalar perturbations during the RD era where PBHs are supposed to form. After deriving a general expression for the GW energy density, we investigate an infinite narrow power spectrum of the scalar perturbation and obtain a semi-analytical expression for Ω_{GW}. Our result implies that the third-order correction to the induced GWs accompanying formation of PBH DM will generate detectable effects on the waveform and the amplitude in observation data. The third-order correction not only enhances the magnitude of Ω_{GW}, but also extends the cutoff frequency from $2f_*$ to $3f_*$. We also explore the constraints on the PBH abundance by LISA and PTA observations, including IPTA, FAST and SKA. These planned GW projects cover a wide frequency band from 10^{-9} Hz to 10^{-3} Hz corresponding to PBHs with mass range $10^{-18} M_\odot - 10^2 M_\odot$. Our results show that the third-order correction could not only lead to an increase in the relative SNR around 10% for these planned GW projects, but also extend the maximum detectable PBH mass. On the other hand, if these projects are unable to detect such induced GWs, we could rule out PBH DM in a wide mass ranges of $\sim 10^{-18} M_\odot - 10 M_\odot$.
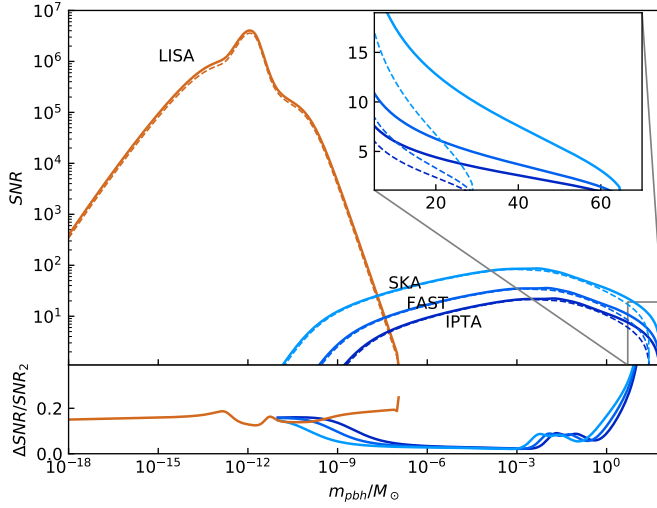

FIG. 2. The upper panel shows the expected SNR of the scalar-induced GWs as a function of $m_{\rm pbh}$ for LISA, IPTA, FAST and SKA. The solid and dashed lines represent the SNR including the third-order correction and only the second-order effects, respectively. The lower panel shows the relative change of the SNR after taking into account the third-order correction.
